

CS 1678: Deep Learning
Introduction

Prof. Adriana Kovashka
University of Pittsburgh
January 19, 2021

About the Instructor

Born 1985 in
Sofia, Bulgaria

Got BA in 2008 at
Pomona College, CA
(Computer Science &
Media Studies)

Got PhD in 2014
at University of
Texas at Austin
(Computer Vision)

Course Info

- **Course website:** https://people.cs.pitt.edu/~kovashka/cs1678_sp21
- **Instructor:** Adriana Kovashka (kovashka@cs.pitt.edu)
 - Use "CS1678" at the beginning of your Subject
- **Office:** Same Zoom link
- **Class:** Tue/Thu, 2:50pm-4:05pm
- **Office hours:**
 - Tue/Thu, 9am-11am, 1-2pm
- **TA:** TBD
- **TA's office:** Zoom link TBD
- **TA's office hours:** TBD (Do Doodle by end of Jan. 24)

Course Goals

- To develop intuitions for machine learning techniques and challenges, in the context of deep neural networks
- To learn the basic techniques, including the math behind basic neural network operations
- To become familiar with advances/specialized neural frameworks (e.g. convolutional/recurrent/transformer)
- To understand advantages/disadvantages of methods
- To practice implementing and using these techniques for simple problems
- To develop practical solutions for one real problem (course project)

Textbooks

- Ian Goodfellow, Yoshua Bengio, Aaron Courville. *Deep Learning*. MIT Press, 2016.
[online version](#)
- Additional readings from papers
- Important: Your notes from class are your best study material, slides are not complete with notes

Programming Language/Frameworks

- We'll use Python, NumPy, and PyTorch
- The TA will do a PyTorch tutorial

Computing Resources

- Will use Google Colab (free) and cloud credits (for project)

Course Structure

- Lectures
- Three programming assignments
- Course project (teams of 3-4)
 - Proposal – early February
 - Report 1 – early March
 - Report 2 – late March
 - Presentations – April (last three classes)
- Quizzes (daily)
- Participation

Tips for a successful project

- From your perspective:
 - Learn something
 - Try something out for a real problem
 - Reminder: sample list of project ideas on Canvas

Tips for a successful project

- From your classmates' perspective:
 - Hear about a niche of DL we haven't covered, or learn about a niche of DL in more depth
 - Hear about challenges and how you handled them, that they can use in their own work
 - Listen to an engaging presentation on a topic they care about

Tips for a successful project

- From my perspective:
 - Hear about the creative solutions you came up with to handle challenges
 - Hear your perspective on a topic that I care about
 - Co-author a publication with you, potentially with a small amount of follow-up work – a really good deal, and looks good on your CV!

Tips for a successful project

- Summary
 - Don't reinvent the wheel – your audience will be bored
 - But it's ok to adapt an existing method to a new domain/problem...
 - If you show interesting experimental results...
 - You analyze them and present them in a clear and engaging fashion

Policies and Schedule

See course website!

Should I take this class?

- It will be a lot of work!
 - I expect you'll spend **6-8 hours** on homework or the project each week
 - But you will learn a lot
- Some parts will be hard and require that you pay close attention!
 - Quizzes help ensure we're on the same page
 - Use instructor's and TA's office hours!

Zoom Etiquette

- Please turn your camera on
- Please send me email if you are unable to do so and explain the reason

Your Homework

- Read entire course website
- Fill out Doodle for TA's office hours
- Sign up for Piazza
- Do first reading
- **Go through NumPy tutorial**

Questions?

Plan for Today

- Blitz introductions
- What is deep learning
 - Example problems and challenges
- Machine Learning overview
 - ML framework
 - Linear classifiers
 - Elements of a ML algorithm
 - Evaluation and generalization
- Review: Linear algebra and calculus

Blitz introductions (10 sec)

- What is your name?
- What one thing outside of school are you passionate about?
- What do you hope to get out of this class?
- **Every time you speak, please remind me your name**

What is deep learning?

- One approach to finding patterns and relationships in data
- Finding the right representations of the data, that enable correct automatic performance of a given task
- Examples: Learn to predict the category (label) of an image, learn to translate between languages

Example deep learning tasks

- Face recognition

Example deep learning tasks

- Image captioning

Factual:

A brown dog drinks from a body of water.

Humorous:

A dog putting his legs into a pond, but scared of the water.

Romantic:

A brown dog steps into murky water, careful to swim back to his master.

Positive:

A cuddly dog is drinking from a body of tranquil water.

Negative:

A black ugly dog drinks from a body of dirty water.

PANDARUS:

Alas, I think he shall be come approached and the day
When little strain would be attain'd into being never fed,
And who is but a chain and subjects of his death,
I should not sleep.

Second Senator:

They are away this miseries, produced upon my soul,
Breaking and strongly should be buried, when I perish
The earth and thoughts of many states.

DUKE VINCENTIO:

Well, your wit is in the care of side and that.

Second Lord:

They would be ruled after this chamber, and
my fair nudes begun out of the fact, to be conveyed,
Whose noble souls I'll have the heart of the wars.

Clown:

Come, sir, I will make did behold your worship.

VIOLA:

I'll drink it.

VIOLA:

Why, Salisbury must find his flesh and thought
That which I am not apt, not a man and in fire,
To show the reining of the raven and the wars
To grace my hand reproach within, and not a fair are hand,
That Caesar and my goodly father's world;
When I was heaven of presence and our fleets,
We spare with hours, but cut thy council I am great,
Murdered and by thy master's ready there
My power to give thee but so much as hell:
Some service in the noble bondman here,
Would show him to her wine.

KING LEAR:

O, if you were a feeble sight, the courtesy of your law,
Your sight and several breath, will wear the gods
With his heads, and my hands are wonder'd at the deeds,
So drop upon your lordship's head, and your opinion
Shall be against your honour.

Why Bitcoin is a great investment

June 6, 2019 - Paul Krugman

As most of my readers know, I'm an optimist.

This belief applies across my life, and to various investments as well. So I am intrigued by the success of cryptocurrencies, such as Bitcoin and Ethereum. The competition they are putting up against the gold standard looks insane, as Bitcoin goes off to the races.

There's no way to fully understand what's going on in the crypto world — and I am not even sure anyone could if you tried to. Still, I can tell you that Bitcoin's recent surge is really an opportunity to buy long-term real assets.

Cryptocurrencies are new and don't even have a useful underlying technology. They will probably fail, probably sooner than later. If people forget about them quickly, it is likely to be because the underlying

Example deep learning tasks

- Question answering

What color are her eyes?
What is the mustache made of?

How many slices of pizza are there?
Is this a vegetarian pizza?

Is this person expecting company?
What is just under the tree?

Does it appear to be rainy?
Does this person have 20/20 vision?

From Recognition to Cognition: Visual Commonsense Reasoning

[♦]Paul G. Allen School of Computer Science & Engineering, University of Washington

[♥]Allen Institute for Artificial Intelligence

visualcommonsense.com

Why is [person4] pointing at [person1]?

- a) He is telling [person3] that [person1] ordered the pancakes.
- b) He just told a joke.
- c) He is feeling accusatory towards [person1].
- d) He is giving [person1] directions.

I chose a) because...

- a) [person1] has the pancakes in front of him.
- b) [person4] is taking everyone's order and asked for clarification.
- c) [person3] is looking at the pancakes and both she and [person2] are smiling slightly.
- d) [person3] is delivering food to the table, and she might not know whose order is whose.

How did [person2] get the money that's in front of her?

- a) [person2] is selling things on the street.
- b) [person2] earned this money playing music.
- c) She may work jobs for the mafia.
- d) She won money playing poker.

I chose b) because...

- a) She is playing guitar for money.
- b) [person2] is a professional musician in an orchestra.
- c) [person2] and [person1] are both holding instruments, and were probably busking for that money.
- d) [person1] is putting money in [person2]'s tip jar, while she plays music.

Figure 1: **VCR**: Given an image, a list of regions, and a question, a model must answer the question and provide a *rationale* explaining why its answer is right. Our questions challenge computer vision systems to go beyond recognition-level understanding, towards a higher-order cognitive and commonsense understanding of the world depicted by the image.

Klingon vs Mlingon Classification

- Training Data
 - Klingon: klix, kour, koop
 - Mlingon: moo, maa, mou
- Testing Data: kap
- Which language? Why?

“I saw her duck”

“I saw her duck”

“I saw her duck”

“I saw her duck with a telescope...”

What humans see

What computers see

Challenges

- Some challenges: ambiguity and context
- Machines take data representations too literally
- Humans are much better than machines at generalization, which is needed since test data will rarely look exactly like the training data

Machine Learning Overview

- Deep learning is a specific group of algorithms falling in the broader realm of machine learning
- All ML/DL algorithms roughly match schema:
 - Learn a mapping from input to output $f: x \rightarrow y$
 - x : image, text, etc.
 - y : {cat, notcat}, {1, 1.5, 2, ...}, etc.
 - f : this is where the magic happens

Machine Learning Overview

$$y' = f(x)$$

A diagram illustrating the machine learning equation $y' = f(x)$. The equation is written in blue. Below it, three red arrows point upwards to the components: the first arrow points to y' and is labeled "output"; the second arrow points to f and is labeled "prediction function"; the third arrow points to x and is labeled "input".

- **Training:** given a *training set* of labeled examples $\{(\mathbf{x}_1, y_1), \dots, (\mathbf{x}_N, y_N)\}$, estimate the prediction function f by minimizing the prediction error on the training set
- **Testing:** apply f to a never before seen *test example* $\mathbf{x}$ and output the predicted value $y' = f(\mathbf{x})$

Machine Learning Overview

- Example:
 - Predict whether an email is spam or not:

From Miss Nadia BamBa,

January 19, 2015 5:57 AM
[Hide Details](#)

From Miss Nadia BamBa,

Greeting, Permit me to inform you of my desire of going into business relationship with you. I am Nadia BamBa the only Daughter of late Mr and Mrs James BamBa, My father was a director of cocoa merchant in Abidjan, the economic capital of Ivory Coast before he was poisoned to death by his business associates on one of their outing to discus on a business deal. When my mother died on the 21st October 2002, my father took me very special because i am motherless.

Before the death of my father in a private hospital here in Abidjan, He secretly called me on his bedside and told me that he had a sum of \$6, 8000.000(SIX Million EIGHT HUNDRED THOUSAND), Dollars) left in a suspense account in a Bank here in Abidjan, that he used my name as his first Daughter for the next of kin in deposit of the fund.

He also explained to me that it was because of this wealth and some huge amount of money That his business associates supposed to balance him from the deal they had that he was poisoned by his business associates, that I should seek for a God fearing foreign partner in a country of my choice where I will transfer this money and use it for investment purposes, (such as real estate Or Hotel management).please i am honourably seeking your assistance in the following ways.

- 1) To provide a Bank account where this money would be transferred to.
- 2) To serve as the guardian of this Money since I am a girl of 19 years old.
- 3)Your private phone number's and your family background' s that we can know each order more.

Machine Learning Overview

- Example:
 - Predict whether an email is spam or not.
 - $\mathbf{x}$ = words in the email, one-hot representation of size $|V| \times 1$, where V is the full vocabulary and $x(j) = 1$ iff word j is mentioned
 - $y = 1$ (if spam) or 0 (if not spam)
 - $y' = f(\mathbf{x}) = \mathbf{w}^T \mathbf{x}$
 - $\mathbf{w}$ is a vector of the same size as $\mathbf{x}$
 - One weight per dimension of $\mathbf{x}$ (i.e. one weight per word)
 - Weight can be positive, zero, negative...
 - What might these weights look like?

Simple strategy: Let's count!

This is X

$$\begin{pmatrix} \text{free} & 100 \\ \text{money} & 2 \\ \vdots & \vdots \\ \text{account} & 2 \\ \vdots & \vdots \end{pmatrix}$$

This is Y

= 1 or 0?

$$\begin{pmatrix} 100 \times 0.2 \\ 2 \times 0.3 \\ \vdots \\ 2 \times 0.3 \\ \vdots \end{pmatrix}$$

$$\begin{pmatrix} \text{free} & 100 \\ \text{money} & 2 \\ \vdots & \vdots \\ \text{account} & 2 \\ \vdots & \vdots \end{pmatrix}$$

This is a *linear classifier*

Machine Learning Overview

- Example:
 - Apply a prediction function to an image to get the desired label output:

$f(\text{apple image}) = \text{"apple"}$

$f(\text{tomato image}) = \text{"tomato"}$

$f(\text{cow image}) = \text{"cow"}$

Machine Learning Overview

- Example:
 - $\mathbf{x}$ = pixels of the image (concatenated to form a vector)
 - y = integer (1 = apple, 2 = tomato, etc.)
 - $y' = f(\mathbf{x}) = \mathbf{w}^T \mathbf{x}$
 - $\mathbf{w}$ is a vector of the same size as $\mathbf{x}$
 - One weight per each dimension of $\mathbf{x}$ (i.e. one weight per pixel)

Linear classifier

- Find a *linear function* to separate the classes

$$f(\mathbf{x}) = \text{sgn}(w_1x_1 + w_2x_2 + \dots + w_Dx_D) = \text{sgn}(\mathbf{w} \cdot \mathbf{x})$$

Linear classifier

- Decision = $\text{sign}(w^T x) = \text{sign}(w_1 x_1 + w_2 x_2)$

- What should the weights be?

Lines in $\mathbb{R}^2$

Let $\mathbf{w} = \begin{bmatrix} a \\ c \end{bmatrix}$ $\mathbf{x} = \begin{bmatrix} x \\ y \end{bmatrix}$

$$ax + cy + b = 0$$

$$\mathbf{w} \cdot \mathbf{x} + b = 0$$

$$D = \frac{|ax_0 + cy_0 + b|}{\sqrt{a^2 + c^2}} = \frac{|\mathbf{w}^T \mathbf{x} + b|}{\|\mathbf{w}\|} \left. \vphantom{\frac{|\mathbf{w}^T \mathbf{x} + b|}{\|\mathbf{w}\|}} \right\} \text{distance from point to line}$$

Linear classifiers

- Find linear function to separate positive and negative examples

Support vector machines

- Discriminative classifier based on *optimal separating line* (for 2d case)
- Maximize the *margin* between the positive and negative training examples

Support vector machines

- Want line that maximizes the margin.

$$\mathbf{x}_i \text{ positive } (y_i = 1): \quad \mathbf{x}_i \cdot \mathbf{w} + b \geq 1$$

$$\mathbf{x}_i \text{ negative } (y_i = -1): \quad \mathbf{x}_i \cdot \mathbf{w} + b \leq -1$$

$$\text{For support, vectors, } \mathbf{x}_i \cdot \mathbf{w} + b = \pm 1$$

$$\text{Distance between point and line: } \frac{|\mathbf{x}_i \cdot \mathbf{w} + b|}{\|\mathbf{w}\|}$$

For support vectors:

$$\frac{\mathbf{w}^T \mathbf{x} + b}{\|\mathbf{w}\|} = \frac{\pm 1}{\|\mathbf{w}\|} \quad M = \left| \frac{1}{\|\mathbf{w}\|} - \frac{-1}{\|\mathbf{w}\|} \right| = \frac{2}{\|\mathbf{w}\|}$$

Finding the maximum margin line

1. Maximize margin $2/\|\mathbf{w}\|$
2. Correctly classify all training data points:

$$\mathbf{x}_i \text{ positive } (y_i = 1): \quad \mathbf{x}_i \cdot \mathbf{w} + b \geq 1$$

$$\mathbf{x}_i \text{ negative } (y_i = -1): \quad \mathbf{x}_i \cdot \mathbf{w} + b \leq -1$$

Quadratic optimization problem:

$$\text{Minimize } \frac{1}{2} \mathbf{w}^T \mathbf{w}$$

$$\text{Subject to } y_i(\mathbf{w} \cdot \mathbf{x}_i + b) \geq 1$$

One constraint for each training point.

Note sign trick.

Finding the maximum margin line

- Solution: $\mathbf{w} = \sum_i \alpha_i y_i \mathbf{x}_i$
 $b = y_i - \mathbf{w} \cdot \mathbf{x}_i$ (for any support vector)

- Classification function:

$$\begin{aligned} f(\mathbf{x}) &= \text{sign}(\mathbf{w} \cdot \mathbf{x} + b) \\ &= \text{sign}\left(\sum_i \alpha_i y_i \mathbf{x}_i \cdot \mathbf{x} + b\right) \end{aligned}$$

If $f(\mathbf{x}) < 0$, classify as negative, otherwise classify as positive.

- Notice that it relies on an *inner product* between the test point $\mathbf{x}$ and the support vectors $\mathbf{x}_i$
- (Solving the optimization problem also involves computing the inner products $\mathbf{x}_i \cdot \mathbf{x}_j$ between all pairs of training points)

Inner product

- The decision boundary for the SVM and its optimization depend on the inner product of two data points (vectors):

$$\mathbf{x}_i^T \mathbf{x}_j$$

$$\begin{aligned} f(x) &= \text{sign}(\mathbf{w} \cdot \mathbf{x} + b) \\ &= \text{sign}\left(\sum_i \alpha_i y_i \mathbf{x}_i \cdot \mathbf{x} + b\right) \end{aligned}$$

- The inner product is equal

$$(\mathbf{x}_i^T \mathbf{x}) = \|\mathbf{x}_i\| * \|\mathbf{x}\| \cos \theta$$

If the angle in between them is 0 then: $(\mathbf{x}_i^T \mathbf{x}) = \|\mathbf{x}_i\| * \|\mathbf{x}\|$

If the angle between them is 90 then: $(\mathbf{x}_i^T \mathbf{x}) = 0$

The inner product measures how similar the two vectors are

Nonlinear SVMs

- Datasets that are linearly separable work out great:

- But what if the dataset is just too hard?

- We can map it to a higher-dimensional space:

Nonlinear SVMs

- General idea: the original input space can always be mapped to some higher-dimensional feature space where the training set is separable:

Nonlinear kernel: Example

- Consider the mapping $\varphi(x) = (x, x^2)$

$$\varphi(x) \cdot \varphi(y) = (x, x^2) \cdot (y, y^2) = xy + x^2 y^2$$

$$K(x, y) = xy + x^2 y^2$$

The “Kernel Trick”

- The linear classifier relies on dot product between vectors $K(\mathbf{x}_i, \mathbf{x}_j) = \mathbf{x}_i \cdot \mathbf{x}_j$
- If every data point is mapped into high-dimensional space via some transformation $\Phi: \mathbf{x}_i \rightarrow \phi(\mathbf{x}_i)$, the dot product becomes: $K(\mathbf{x}_i, \mathbf{x}_j) = \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j)$
- A *kernel function* is similarity function that corresponds to an inner product in some expanded feature space
- *The kernel trick*: instead of explicitly computing the lifting transformation $\phi(\mathbf{x})$, define a kernel function K such that: $K(\mathbf{x}_i, \mathbf{x}_j) = \phi(\mathbf{x}_i) \cdot \phi(\mathbf{x}_j)$

Examples of kernel functions

- Linear: $K(x_i, x_j) = x_i^T x_j$

- Polynomials of degree up to d :

$$K(x_i, x_j) = (x_i^T x_j + 1)^d$$

- Gaussian RBF:

$$K(x_i, x_j) = \exp\left(-\frac{\|x_i - x_j\|^2}{2\sigma^2}\right)$$

- Histogram intersection:

$$K(x_i, x_j) = \sum_k \min(x_i(k), x_j(k))$$

Deep Learning in a Nutshell

- Input $\rightarrow$ network $\rightarrow$ outputs
- Input X is raw (e.g. raw image, one-hot representation of text)
- Network extracts features: abstraction of input
- Output is the labels Y
- All parameters of the network trained by checking how well predicted/true Y agree, using labels in the training set

Elements of Machine *Learning*

- Every machine learning algorithm has:
 - Data representation (x, y)
 - Problem representation (network)
 - Evaluation / objective function
 - Optimization (solve for parameters of network)

Data representation

- Let's brainstorm what our “X” should be for various “Y” prediction tasks...

Problem representation

- Instances
- Decision trees
- Sets of rules / Logic programs
- Support vector machines
- Graphical models (Bayes/Markov nets)
- **Neural networks**
- Model ensembles
- Etc.

Evaluation / objective function

- Accuracy
- Precision and recall
- Squared error
- Likelihood
- Posterior probability
- Cost / Utility
- Margin
- Entropy
- K-L divergence
- Etc.

Loss functions

- Measure error
- Can be defined for discrete or continuous outputs
- E.g. if task is classification – could use cross-entropy loss
- If task is regression – use L2 loss i.e. $||y - y'||$

Optimization

- Optimization means we need to solve for the parameters $\mathbf{w}$ of the model
- For a (non-linear) neural network, there is no closed-form solution to solve for $\mathbf{w}$; cannot set up linear system with $\mathbf{w}$ as the unknowns
- Thus, optimization solutions look like this:
 1. Initialize $\mathbf{w}$ (e.g. randomly)
 2. Check error (ground-truth vs predicted labels on training set) under current model
 3. Use gradient (derivative) of error wrt $\mathbf{w}$ to update $\mathbf{w}$
 4. Repeat from 2 until convergence

Types of Learning

- Supervised learning
 - Training data includes desired outputs
- Unsupervised learning
 - Training data does not include desired outputs
- Weakly or Semi-supervised learning
 - Training data includes a few desired outputs, or contains labels that only approximate the labels desired at test time
- Reinforcement learning
 - Rewards from sequence of actions

Types of Prediction Tasks

Supervised Learning

Unsupervised Learning

Validation strategies

- Ultimately, for our application, what do we want?
 - High accuracy on training data?
 - No, high accuracy on *unseen/new/test data*!
 - Why is this tricky?
- Training data
 - Features (x) and labels (y) used to learn mapping f
- Test data
 - Features used to make a prediction
 - Labels only used to see how well we've learned $f!!!$
- Validation data
 - Held-out set of the *training data*
 - Can use both features and labels to tune model *hyperparameters*
 - *Hyperparameters* are “knobs” of the algorithm tuned by the designer: number of iterations for learning, learning rate, etc.
 - We train multiple model (one per hyperparameter setting) and choose the best one, on the validation set

Validation strategies

Idea #1: Choose hyperparameters that work best on the data

BAD: Overfitting; e.g. in K-nearest neighbors, $K = 1$ always works perfectly on training data

Idea #2: Split data into **train** and **test**, choose hyperparameters that work best on test data

BAD: No idea how algorithm will perform on new data; cheating

Idea #3: Split data into **train**, **val**, and **test**; choose hyperparameters on val and evaluate on test

Better!

Validation strategies

Your Dataset

Idea #4: Cross-Validation: Split data into **folds**, try each fold as validation and average the results

fold 1	fold 2	fold 3	fold 4	fold 5	test
fold 1	fold 2	fold 3	fold 4	fold 5	test
fold 1	fold 2	fold 3	fold 4	fold 5	test

Useful for small datasets, but not used too frequently in deep learning

Why do we hope this would work?

- Statistical estimation view:
 - x and y are *random variables*
 - $D = (x_1, y_1), (x_2, y_2), \dots, (x_N, y_N) \sim P(X, Y)$
 - Both training & testing data sampled IID from $P(X, Y)$
 - IID: Independent and Identically Distributed
 - Learn on training set, have some hope of *generalizing* to test set

Generalization

Training set (labels known)

Test set (labels unknown)

- How well does a learned model generalize from the data it was trained on to a new test set?

Generalization

- Underfitting: Models with too few parameters are inaccurate because of a large bias (not enough flexibility).

- Overfitting: Models with too many parameters are inaccurate because of a large variance (too much sensitivity to the sample).

Purple dots = possible test points

Red dots = training data (all that we see before we ship off our model!)

Green curve = true underlying model

Blue curve = our predicted model/fit

Generalization

- Components of generalization error
 - **Noise** in our observations: unavoidable
 - **Bias**: due to inaccurate assumptions/simplifications by model
 - **Variance**: models estimated from different training sets differ greatly from each other
- **Underfitting**: model is too “simple” to represent all the relevant class characteristics
 - High bias and low variance
 - High training error and high test error
- **Overfitting**: model is too “complex” and fits irrelevant characteristics (noise) in the data
 - Low bias and high variance
 - Low training error and high test error

Generalization

Polynomial Curve Fitting

$$y(x, \mathbf{w}) = w_0 + w_1x + w_2x^2 + \dots + w_Mx^M = \sum_{j=0}^M w_jx^j$$

Sum-of-Squares Error Function

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^N \{y(x_n, \mathbf{w}) - t_n\}^2$$

0th Order Polynomial

1st Order Polynomial

3rd Order Polynomial

9th Order Polynomial

Over-fitting

Root-Mean-Square (RMS) Error: $E_{\text{RMS}} = \sqrt{2E(\mathbf{w}^*)/N}$

Data Set Size: $N = 15$

9th Order Polynomial

Data Set Size: $N = 100$

9th Order Polynomial

Regularization

Penalize large coefficient values

$$E(\mathbf{w}) = \frac{1}{2} \sum_{n=1}^N \{y(x_n, \mathbf{w}) - t_n\}^2$$

(Remember: We want to minimize this expression.)

Regularization: $\ln \lambda = -18$

Regularization: $\ln \lambda = 0$

Polynomial Coefficients

	$M = 0$	$M = 1$	$M = 3$	$M = 9$
w_0^*	0.19	0.82	0.31	0.35

w_8^*	-557682.99	-91.53	0.00
w_9^*	125201.43	72.68	0.01

Regularization: E_{RMS} vs. $\ln \lambda$

Training vs test error

The effect of training set size

Choosing the trade-off between bias and variance

- Need validation set (separate from the test set)

Summary of generalization

- Try simple classifiers first
- Better to have smart features and simple classifiers than simple features and smart classifiers
- Use increasingly powerful classifiers with more training data
- As an additional technique for reducing variance, try regularizing the parameters

Linear algebra review

See <http://cs229.stanford.edu/section/cs229-linalg.pdf> for more

Vectors and Matrices

- Vectors and matrices are just collections of ordered numbers that represent something: movements in space, scaling factors, word counts, movie ratings, pixel brightnesses, etc.
- We'll define some common uses and standard operations on them.

Vector

- A column vector $\mathbf{v} \in \mathbb{R}^{n \times 1}$ where

$$\mathbf{v} = \begin{bmatrix} v_1 \\ v_2 \\ \vdots \\ v_n \end{bmatrix}$$

- A row vector $\mathbf{v}^T \in \mathbb{R}^{1 \times n}$ where

$$\mathbf{v}^T = [v_1 \quad v_2 \quad \dots \quad v_n]$$

T denotes the transpose operation

- You need to keep track of orientation

Vectors have two main uses

- Vectors can represent an offset in 2D or 3D space
- Points are just vectors from the origin
- Data can also be treated as a vector
- Such vectors don't have a geometric interpretation, but calculations like "distance" still have value

Matrix

- A matrix $\mathbf{A} \in \mathbb{R}^{m \times n}$ is an array of numbers with size $m \downarrow$ by $n \rightarrow$, i.e. m rows and n columns.

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & a_{13} & \dots & a_{1n} \\ a_{21} & a_{22} & a_{23} & \dots & a_{2n} \\ \vdots & & & & \vdots \\ a_{m1} & a_{m2} & a_{m3} & \dots & a_{mn} \end{bmatrix}$$

- If $m = n$, we say that $\mathbf{A}$ is square.

Matrix Operations

- Addition

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} + \begin{bmatrix} 1 & 2 \\ 3 & 4 \end{bmatrix} = \begin{bmatrix} a + 1 & b + 2 \\ c + 3 & d + 4 \end{bmatrix}$$

- Can only add a matrix with matching dimensions, or a scalar.

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} + 7 = \begin{bmatrix} a + 7 & b + 7 \\ c + 7 & d + 7 \end{bmatrix}$$

- Scaling

$$\begin{bmatrix} a & b \\ c & d \end{bmatrix} \times 3 = \begin{bmatrix} 3a & 3b \\ 3c & 3d \end{bmatrix}$$

Inner vs outer vs matrix vs element-wise product

- $\mathbf{x}, \mathbf{y}$ = column vectors ($n \times 1$)
- $\mathbf{X}, \mathbf{Y}$ = matrices ($m \times n$)
- x, y = scalars (1×1)
- $\mathbf{x} \cdot \mathbf{y} = \mathbf{x}^T \mathbf{y}$ = inner product ($1 \times n \times n \times 1 = \text{scalar}$)
- $\mathbf{x} \otimes \mathbf{y} = \mathbf{x} \mathbf{y}^T$ = outer product ($n \times 1 \times 1 \times n = \text{matrix}$)
- $\mathbf{X} * \mathbf{Y}$ = matrix product
 - Watch out: could also be element-wise product in NumPy, if class is array rather than matrix— see tutorial

Inner Product

- Multiply corresponding entries of two vectors and add up the result

$$\mathbf{x}^T \mathbf{y} = \begin{bmatrix} x_1 & \dots & x_n \end{bmatrix} \begin{bmatrix} y_1 \\ \vdots \\ y_n \end{bmatrix} = \sum_{i=1}^n x_i y_i \quad (\text{scalar})$$

- $\mathbf{x} \cdot \mathbf{y}$ is also $|\mathbf{x}| |\mathbf{y}| \cos(\text{angle between } \mathbf{x} \text{ and } \mathbf{y})$
- If $\mathbf{B}$ is a unit vector, then $\mathbf{A} \cdot \mathbf{B}$ gives the length of $\mathbf{A}$ which lies in the direction of $\mathbf{B}$ (projection)

Matrix Multiplication

- Let X be an $a \times b$ matrix, Y be an $b \times c$ matrix
- Then $Z = X * Y$ is an $a \times c$ matrix
- Second dimension of first matrix, and first dimension of second matrix have to be the same, for matrix multiplication to be possible
- Practice: Let X be an 10×5 matrix. Let's factorize it into 3 matrices...

Matrix Multiplication

- The product AB is:

- Each entry in the result is (that row of A) dot product with (that column of B)

Matrix Multiplication

- Example:

$$\begin{array}{ccc} A & \times & B \\ \downarrow & & \searrow \\ \begin{bmatrix} 0 & 2 \\ 4 & 6 \end{bmatrix} & & \begin{bmatrix} 1 & 3 \\ 5 & 7 \end{bmatrix} \end{array}$$

The diagram illustrates the first step of matrix multiplication. Matrix A is $\begin{bmatrix} 0 & 2 \\ 4 & 6 \end{bmatrix}$ and matrix B is $\begin{bmatrix} 1 & 3 \\ 5 & 7 \end{bmatrix}$. An arrow points from the first row of A to the first row of the resulting matrix, and another arrow points from the first column of B to the first column of the resulting matrix. The resulting matrix is $\begin{bmatrix} \square & 14 \\ \square & \square \end{bmatrix}$, where the value 14 is highlighted in yellow.

$$0 \cdot 3 + 2 \cdot 7 = 14$$

- Each entry of the matrix product is made by taking the dot product of the corresponding row in the left matrix, with the corresponding column in the right one.

Matrix Operation Properties

- Matrix addition is commutative and associative
 - $A + B = B + A$
 - $A + (B + C) = (A + B) + C$
- Matrix multiplication is associative and distributive but *not* commutative
 - $A(B * C) = (A * B)C$
 - $A(B + C) = A * B + A * C$
 - $A * B \neq B * A$

Matrix Operations

- Transpose – flip matrix, so row 1 becomes column 1

The diagram shows a matrix $\begin{bmatrix} 0 & 1 & \dots \end{bmatrix}$ with a dashed diagonal line and a blue arrow pointing from the top-left to the bottom-right, illustrating the transpose operation.

$$\begin{bmatrix} 0 & 1 \\ 2 & 3 \\ 4 & 5 \end{bmatrix}^T = \begin{bmatrix} 0 & 2 & 4 \\ 1 & 3 & 5 \end{bmatrix}$$

- A useful identity:

$$(ABC)^T = C^T B^T A^T$$

Inverse

- Given a matrix $\mathbf{A}$, its inverse $\mathbf{A}^{-1}$ is a matrix such that $\mathbf{A}\mathbf{A}^{-1} = \mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$
- E.g. $\begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix}^{-1} = \begin{bmatrix} \frac{1}{2} & 0 \\ 0 & \frac{1}{3} \end{bmatrix}$
- Inverse does not always exist. If $\mathbf{A}^{-1}$ exists, $\mathbf{A}$ is *invertible* or *non-singular*. Otherwise, it's *singular*.

Special Matrices

- Identity matrix $\mathbf{I}$
 - Square matrix, 1's along diagonal, 0's elsewhere
 - $\mathbf{I} \cdot [\text{another matrix}] = [\text{that matrix}]$

$$\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

- Diagonal matrix
 - Square matrix with numbers along diagonal, 0's elsewhere
 - A diagonal $\cdot$ [another matrix] scales the rows of that matrix

$$\begin{bmatrix} 3 & 0 & 0 \\ 0 & 7 & 0 \\ 0 & 0 & 2.5 \end{bmatrix}$$

Special Matrices

- Symmetric matrix

$$\mathbf{A}^T = \mathbf{A}$$

$$\begin{bmatrix} 1 & 2 & 5 \\ 2 & 1 & 7 \\ 5 & 7 & 1 \end{bmatrix}$$

Norms

- L1 norm

$$\|\mathbf{x}\|_1 := \sum_{i=1}^n |x_i|$$

- L2 norm

$$\|\mathbf{x}\| := \sqrt{x_1^2 + \cdots + x_n^2}$$

- L^p norm (for real numbers $p \geq 1$)

$$\|\mathbf{x}\|_p := \left(\sum_{i=1}^n |x_i|^p \right)^{1/p}$$

System of Linear Equations

- MATLAB example

// linalg.solve or linalg.lstsq in Python

$$AX = B$$

$$A = \begin{bmatrix} 2 & 2 \\ 3 & 4 \end{bmatrix}, B = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

```
>> x = A\B
```

```
x =
```

```
    1.0000
```

```
   -0.5000
```

Matrix Rank

- Column/row rank

$\text{col-rank}(\mathbf{A}) =$ the maximum number of linearly independent column vectors of $\mathbf{A}$

$\text{row-rank}(\mathbf{A}) =$ the maximum number of linearly independent row vectors of $\mathbf{A}$

- Column rank always equals row rank
- Matrix rank $\text{rank}(\mathbf{A}) \triangleq \text{col-rank}(\mathbf{A}) = \text{row-rank}(\mathbf{A})$
- If a matrix is not full rank, inverse doesn't exist
 - Inverse also doesn't exist for non-square matrices

Linear independence

- Suppose we have a set of vectors $\mathbf{v}_1, \dots, \mathbf{v}_n$
- If we can express $\mathbf{v}_1$ as a linear combination of the other vectors $\mathbf{v}_2 \dots \mathbf{v}_n$, then $\mathbf{v}_1$ is linearly *dependent* on the other vectors.
 - The direction $\mathbf{v}_1$ can be expressed as a combination of the directions $\mathbf{v}_2 \dots \mathbf{v}_n$. (E.g. $\mathbf{v}_1 = .7 \mathbf{v}_2 - .5 \mathbf{v}_4$)
- If no vector is linearly dependent on the rest of the set, the set is linearly *independent*.
 - Common case: a set of vectors $\mathbf{v}_1, \dots, \mathbf{v}_n$ is always linearly independent if each vector is perpendicular to every other vector (and non-zero)

Linear independence

Linearly independent set

Not linearly independent

Singular Value Decomposition (SVD)

- There are several computer algorithms that can “factor” a matrix, representing it as the product of some other matrices
- The most useful of these is the Singular Value Decomposition
- Represents any matrix **A** as a product of three matrices: **$U\Sigma V^T$**

Singular Value Decomposition (SVD)

$$\mathbf{U}\mathbf{\Sigma}\mathbf{V}^T = \mathbf{A}$$

- Where $\mathbf{U}$ and $\mathbf{V}$ are rotation matrices, and $\mathbf{\Sigma}$ is a scaling matrix. For example:

$$\begin{matrix} U & & \Sigma & & V^T & & A \\ \begin{bmatrix} -.40 & .916 \\ .916 & .40 \end{bmatrix} & \times & \begin{bmatrix} 5.39 & 0 \\ 0 & 3.154 \end{bmatrix} & \times & \begin{bmatrix} -.05 & .999 \\ .999 & .05 \end{bmatrix} & = & \begin{bmatrix} 3 & -2 \\ 1 & 5 \end{bmatrix} \end{matrix}$$

Singular Value Decomposition (SVD)

- In general, if $\mathbf{A}$ is $m \times n$, then $\mathbf{U}$ will be $m \times m$, $\mathbf{\Sigma}$ will be $m \times n$, and $\mathbf{V}^T$ will be $n \times n$.

$$\begin{matrix} U \\ \begin{bmatrix} -.39 & -.92 \\ -.92 & .39 \end{bmatrix} \end{matrix} \times \begin{matrix} \Sigma \\ \begin{bmatrix} 9.51 & 0 & 0 \\ 0 & .77 & 0 \end{bmatrix} \end{matrix} \times \begin{matrix} V^T \\ \begin{bmatrix} -.42 & -.57 & -.70 \\ .81 & .11 & -.58 \\ .41 & -.82 & .41 \end{bmatrix} \end{matrix} = \begin{matrix} A \\ \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix} \end{matrix}$$

Singular Value Decomposition (SVD)

- **U** and **V** are always rotation matrices.
 - Geometric rotation may not be an applicable concept, depending on the matrix. So we call them “unitary” matrices – each column is a unit vector.
- **Σ** is a diagonal matrix
 - The number of nonzero entries = rank of **A**
 - The algorithm always sorts the entries high to low

$$\begin{matrix} U & & \Sigma & & V^T & & A \\ \begin{bmatrix} -.39 & -.92 \\ -.92 & .39 \end{bmatrix} & \times & \begin{bmatrix} 9.51 & 0 & 0 \\ 0 & .77 & 0 \end{bmatrix} & \times & \begin{bmatrix} -.42 & -.57 & -.70 \\ .81 & .11 & -.58 \\ .41 & -.82 & .41 \end{bmatrix} & = & \begin{bmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{bmatrix}
 \end{matrix}$$

Singular Value Decomposition (SVD)

$$\mathbf{M} = \mathbf{U}\mathbf{\Sigma}\mathbf{V}^T$$

Calculus review

Differentiation

The derivative provides us information about the rate of change of a function.

The derivative of a function is also a function.

Example:

The derivative of the rate function is the acceleration function.

Derivative = rate of change

Derivative = rate of change

- Linear function $y = mx + b$
- Slope $m = \frac{\text{change in } y}{\text{change in } x} = \frac{\Delta y}{\Delta x}$,

Ways to Write the Derivative

Given the function $f(x)$, we can write its derivative in the following ways:

- $f'(x)$
- $\frac{d}{dx}f(x)$

The derivative of x is commonly written dx .

Differentiation Formulas

The following are common differentiation formulas:

- The derivative of a constant is 0.

$$\frac{d}{du} c = 0$$

- The derivative of a sum is the sum of the derivatives.

$$\frac{d}{du} (f(u) + g(u)) = f'(u) + g'(u)$$

Examples

- The derivative of a constant is 0.

$$\frac{d}{du} 7 =$$

- The derivative of a sum is the sum of the derivatives.

$$\frac{d}{dt} (t + 4) =$$

More Formulas

- The derivative of u to a constant power:

$$\frac{d}{du} u^n = n * u^{n-1} du$$

- The derivative of e :

$$\frac{d}{du} e^u = e^u du$$

- The derivative of $\log$:

$$\frac{d}{du} \log(u) = \frac{1}{u} du$$

More Examples

- The derivative of u to a constant power:

$$\frac{d}{dx} 3x^3 =$$

- The derivative of e :

$$\frac{d}{dy} e^{4y} =$$

- The derivative of $\log$:

$$\frac{d}{dx} 3\log(x) =$$

Product and Quotient

The product rule and quotient rules are commonly used in differentiation.

- Product rule:

$$\frac{d}{du} (f(u) * g(u)) = f(u)g'(u) + g(u)f'(u)$$

- Quotient rule:

$$\frac{d}{du} \left(\frac{f(u)}{g(u)} \right) = \frac{g(u)f'(u) - f(u)g'(u)}{(g(u))^2}$$

Chain Rule

The chain rule allows you to combine any of the differentiation rules we have already covered.

- First, do the derivative of the outside and then do the derivative of the inside.

$$\frac{d}{du} f(g(u)) = f'(g(u)) * g'(u) * du$$

Try These

$$f(z) = z + 11$$

$$s(y) = 4ye^{2y}$$

$$g(y) = 4y^3 + 2y$$

$$p(x) = \frac{\log(x^2)}{x}$$

$$h(x) = e^{3x}$$

$$q(z) = (e^z - z)^3$$

Solutions

$$f'(z) = 1$$

$$s'(y) = 8ye^{2y} + 4e^{2y}$$

$$g'(y) = 12y^2 + 2$$

$$p'(x) = \frac{2 - \log(x^2)}{x^2}$$

$$h'(x) = 3e^{3x}$$

$$q'(z) = 3(e^z - z)^2(e^z - 1)$$
