### Administration

- **PS-1 due today**
  - Report before the class begins
  - Programs through ftp
- **PS-2 is out**
  - on the course web page
  - due next week on Tuesday, September 16, 2003
    - Report
    - Programs

---

CS 1571 Intro to AI

## Evaluation-function driven search

- A search strategy can be defined in terms of **a node evaluation function**
- **Evaluation function**
  - Denoted  $f(n)$
  - Defines the desirability of a node to be expanded next
- **Evaluation-function driven search: expand the node (state) with the best evaluation-function value**
- **Implementation:** successors of the expanded node are inserted into the **priority queue** in the decreasing order of their evaluation function value

## Uniform cost search

- **Uniform cost search (Dijkstra's shortest path):**
  - A special case of the evaluation-function driven search
$$f(n) = g(n)$$
- **Path cost function**  $g(n)$  ;
  - path cost from the initial state to  $n$
- **Uniform-cost search:**
  - Can handle general minimum cost path-search problem:
  - **weights or costs** associated with operators (links).
- **Note:** Uniform cost search relies on the problem definition only
  - It is an uninformed search method

## Best-first search

### Best-first search

- incorporates a **heuristic function**,  $h(n)$ , into the evaluation function  $f(n)$  to guide the search.

### Heuristic function:

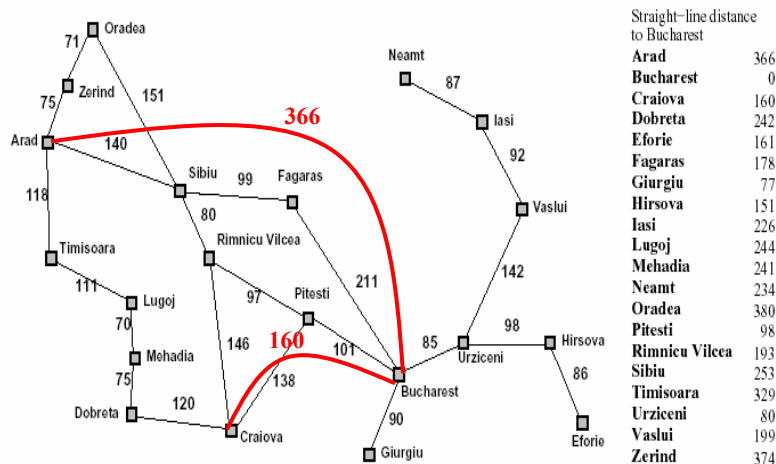

- Measures a potential of a state (node) to reach a goal
- Typically in terms of some distance to a goal estimate

### Example of a heuristic function:

- Assume a shortest path problem with city distances on connections
- Straight-line distances between cities give additional information we can use to guide the search

CS 1571 Intro to AI

### Example: traveler problem with straight-line distance information

- Straight-line distances** give an estimate of the cost of the path between the two cities

CS 1571 Intro to AI

## Best-first search

### Best-first search

- incorporates a **heuristic function**,  $h(n)$ , into the evaluation function  $f(n)$  to guide the search.
- **heuristic function**: measures a potential of a state (node) to reach a goal

**Special cases** (differ in the design of evaluation function):

- **Greedy search**

$$f(n) = h(n)$$

- **A\* algorithm**

$$f(n) = g(n) + h(n)$$

- + **iterative deepening** version of A\* : **IDA\***

## Greedy search method

- Evaluation function is equal to the heuristic function

$$f(n) = h(n)$$

- **Idea**: the node that seems to be the closest to the goal is expanded first

## Greedy search

$$f(n)=h(n)$$

queue → 

Arad	366
------	-----

## Greedy search

$$f(n)=h(n)$$

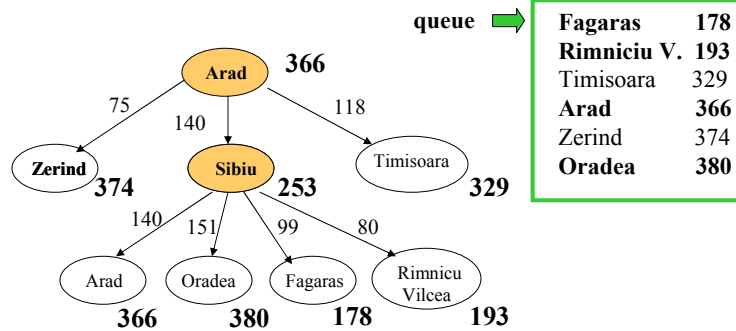

queue → 

Sibiu	253
Timisoara	329
Zerind	374

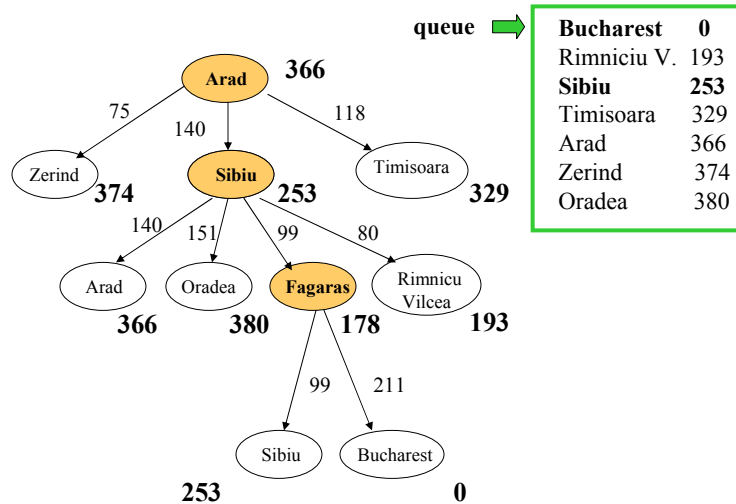

## Greedy search

$$f(n)=h(n)$$

## Greedy search

$$f(n)=h(n)$$

## Properties of greedy search

- **Completeness:** ?
- **Optimality:** ?
- **Time complexity:** ?
- **Memory (space) complexity:** ?

---

CS 1571 Intro to AI

## Properties of greedy search

- **Completeness:** **No.**  
We can loop forever. Nodes that seem to be the best choices can lead to cycles. Elimination of state repeats can solve the problem.
- **Optimality:** **No.**  
Even if we reach the goal, we may be biased by a bad heuristic estimate. Evaluation function disregards the cost of the path built so far.
- **Time complexity:**  $O(b^m)$   
Worst case !!! But often better!
- **Memory (space) complexity:**  $O(b^m)$   
Often better!

---

CS 1571 Intro to AI

## A\* search

- The problem with the greedy search is that it can keep expanding paths that are already very expensive.
- The problem with the uniform-cost search is that it uses only past exploration information (path cost), no additional information is utilized

- **A\* search**

$$f(n) = g(n) + h(n)$$

$g(n)$  - cost of reaching the state

$h(n)$  - estimate of the cost from the current state to a goal

$f(n)$  - estimate of the path length

- **Additional A\*condition:** admissible heuristic

$$h(n) \leq h^*(n) \quad \text{for all } n$$

CS 1571 Intro to AI

## Properties of A\* search

- **Completeness:** ?
- **Optimality:** ?
- **Time complexity:**
  - ?
- **Memory (space) complexity:**
  - ?

## Properties of A\* search

- **Completeness:** Yes.
- **Optimality:** ?
- **Time complexity:**
  - ?
- **Memory (space) complexity:**
  - ?

## Optimality of A\*

- In general, a heuristic function  $h(n)$  :  
Can overestimate, be equal or underestimate the true distance of a node to the goal  $h^*(n)$
- Is the A\* optimal for the arbitrary heuristic function?
- **No !**

- **Admissible heuristic condition**

- **Never overestimate the distance to the goal !!!**

$$h(n) \leq h^*(n) \quad \text{for all } n$$

**Example:** the straight-line distance in the travel problem never overestimates the actual distance

**Claim:** A\* search (with an admissible heuristic !!) is optimal

---

CS 1571 Intro to AI

## Optimality of A\* (proof)

- Let G1 be the optimal goal (with the minimum path distance). Assume that we have a sub-optimal goal G2. Let  $n$  be a node that is on the optimal path and is in the queue together with G2

$$\begin{aligned} \text{Then: } f(G2) &= g(G2) && \text{since } h(G2) = 0 \\ &> g(G1) && \text{since } G2 \text{ is suboptimal} \\ &\geq f(n) && \text{since } h \text{ is admissible} \end{aligned}$$

**And thus A\* never selects G2 before  $n$**

---

CS 1571 Intro to AI

## Properties of A\* search

- Completeness: **Yes.**
- Optimality: **Yes (with the admissible heuristic)**
- Time complexity:
  - ?
- Memory (space) complexity:
  - ?

## Properties of A\* search

- Completeness: **Yes.**
- Optimality: **Yes (with the admissible heuristic)**
- Time complexity:
  - **Order roughly the number of nodes with  $f(n)$  smaller than the cost of the optimal path  $g^*$**
- Memory (space) complexity:
  - **Same as time complexity (all nodes in the memory)**

## Admissible heuristics

- Heuristics are designed based on relaxed version of problems
- **Example:** the 8-puzzle problem

**Initial position**

4	5	
6	1	8
7	3	2

**Goal position**

1	2	3
4	5	6
7	8	

- **Admissible heuristics:**
  1. number of misplaced tiles
  2. Sum of distances of all tiles from their goal positions (Manhattan distance)

## Admissible heuristics

- We can have multiple admissible heuristics for the same problem
- **Dominance:** Heuristic function  $h_1$  dominates  $h_2$  if

$$\forall n \quad h_1(n) \geq h_2(n)$$

- **Combination:** two or more admissible heuristics can be combined to give a new admissible heuristics
  - Assume two admissible heuristics  $h_1, h_2$

$$\text{Then: } h_3(n) = \max(h_1(n), h_2(n))$$

**is admissible**

## IDA\*

### Iterative deepening version of A\*

- Progressively increases the evaluation function limit (instead of the depth limit)
- Performs limited-cost depth-first search for the current evaluation function limit
  - Keeps expanding nodes in the depth first manner up to the evaluation function limit

**Problem:** the amount by which the evaluation limit should be progressively increased

#### Solutions:

- **peak over the previous step boundary** to guarantee that in the next cycle more nodes are expanded
- **Increase the limit by a fixed cost increment – say  $u$**

## IDA\*

**Solution 1: peak over the previous step boundary to guarantee that in the next cycle more nodes are expanded**

#### Properties:

- the choice of the new cost limit influences how many nodes are expanded in each iteration
- We may find a sub-optimal solution
  - **Fix:** complete the search up to the limit to find the best

**Solution 2: Increase the limit by a fixed cost increment ( $u$ )**

#### Properties:

- Too many or too few nodes expanded – no control of the number of nodes
- The solution of accuracy  $< u$  is found
