Lecture 4

Transport Layer

Design Issues and Protocols

Prof. Taieb Znati

Transport Layer Design Issues and Protocols

- ✘ understand principles behind transport layer services:
 - ✘ multiplexing/demultiplexing
 - ✘ reliable data transfer
 - ✘ flow control
 - ✘ congestion control
- ✘ learn about transport layer protocols in the Internet:
 - ✘ UDP: connectionless transport
 - ✘ TCP: connection-oriented transport
 - ✘ TCP congestion control

Outline

- ✘ Transport-layer services
- ✘ Multiplexing and demultiplexing
- ✘ Connectionless transport: UDP
- ✘ Connection-oriented transport: TCP
 - ✘ segment structure
 - ✘ reliable data transfer
 - ✘ flow control
 - ✘ connection management
- ✘ Principles of congestion control
- ✘ TCP congestion control

Transport services and protocols

- ✘ provide *logical communication* between app processes running on different hosts
- ✘ transport protocols run in end systems
 - ✘ send side: breaks app messages into **segments**, passes to network layer
 - ✘ rcv side: reassembles segments into messages, passes to app layer
- ✘ more than one transport protocol available to apps
 - ✘ Internet: TCP and UDP

Transport vs. network layer

- ✘ *network layer*: logical communication between hosts
- ✘ *transport layer*: logical communication between processes
 - ✘ relies on, enhances, network layer services

Household analogy:

12 kids sending letters to 12 kids

- ✘ processes = kids
- ✘ app messages = letters in envelopes
- ✘ hosts = houses
- ✘ transport protocol = Ann and Bill
- ✘ network-layer protocol = postal service

Internet transport-layer protocols

- ✘ reliable, in-order delivery (TCP)
 - ✘ congestion control
 - ✘ flow control
 - ✘ connection setup
- ✘ unreliable, unordered delivery: UDP
 - ✘ no-frills extension of “best-effort” IP
- ✘ services not available:
 - ✘ delay guarantees
 - ✘ bandwidth guarantees

Outline

- ✘ Transport-layer services
- ✘ **Multiplexing and demultiplexing**
- ✘ Connectionless transport: UDP
- ✘ 3.5 Connection-oriented transport: TCP
 - ✘ segment structure
 - ✘ reliable data transfer
 - ✘ flow control
 - ✘ connection management
- ✘ 3.6 Principles of congestion control
- ✘ 3.7 TCP congestion control

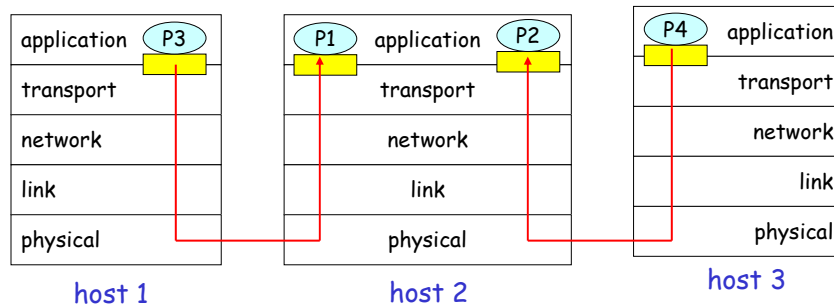

Multiplexing/demultiplexing

Demultiplexing at rcv host:
delivering received segments to correct socket

Multiplexing at send host:
gathering data from multiple sockets, enveloping data with header (later used for demultiplexing)

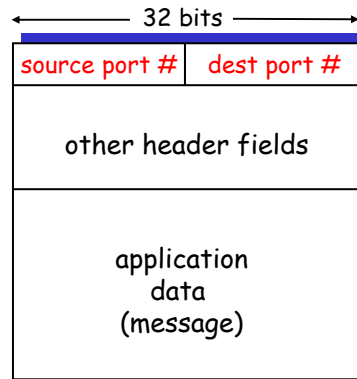

■ = socket ○ = process

How demultiplexing works

- ✘ **host receives IP datagrams**
 - ✘ each datagram has source IP address, destination IP address
 - ✘ each datagram carries 1 transport-layer segment
 - ✘ each segment has source, destination port number (recall: well-known port numbers for specific applications)
- ✘ **host uses IP addresses & port numbers to direct segment to appropriate socket**

TCP/UDP segment format

Connectionless demultiplexing

- ✘ **Create sockets with port numbers:**

```
DatagramSocket mySocket1 = new
  DatagramSocket(99111);
DatagramSocket mySocket2 = new
  DatagramSocket(99222);
```
- ✘ **UDP socket identified by two-tuple:**
(dest IP address, dest port number)
- ✘ **When host receives UDP segment:**
 - ✘ checks destination port number in segment
 - ✘ directs UDP segment to socket with that port number
- ✘ **IP datagrams with different source IP addresses and/or source port numbers directed to same socket**

Connectionless demux (cont)

```
DatagramSocket serverSocket = new DatagramSocket(6428);
```

SP provides "return address"

Connection-oriented demux

- ✘ TCP socket identified by 4-tuple:
 - ✘ source IP address
 - ✘ source port number
 - ✘ dest IP address
 - ✘ dest port number
- ✘ recv host uses all four values to direct segment to appropriate socket
- ✘ Server host may support many simultaneous TCP sockets:
 - ✘ each socket identified by its own 4-tuple
- ✘ Web servers have different sockets for each connecting client
 - ✘ non-persistent HTTP will have different socket for each request

Connection-oriented demux (cont)

Fall '06-02

TELCOM 2310

13

Outline

- ✘ Transport-layer services
- ✘ Multiplexing and demultiplexing
- ✘ **Connectionless transport: UDP**
- ✘ 3.5 Connection-oriented transport: TCP
 - ✘ segment structure
 - ✘ reliable data transfer
 - ✘ flow control
 - ✘ connection management
- ✘ 3.6 Principles of congestion control
- ✘ 3.7 TCP congestion control

Fall '06-02

TELCOM 2310

14

UDP: User Datagram Protocol [RFC 768]

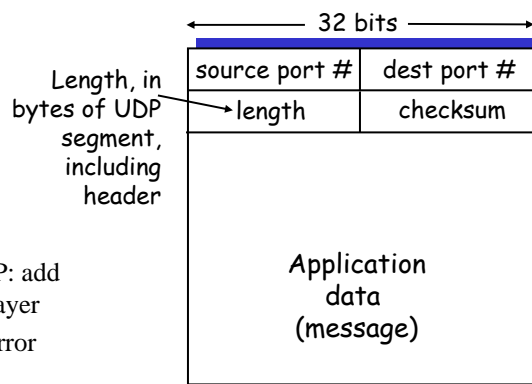

- ✘ “no frills,” “bare bones” Internet transport protocol
- ✘ “best effort” service, UDP segments may be:
 - ✘ lost
 - ✘ delivered out of order to app
- ✘ *connectionless*:
 - ✘ no handshaking between UDP sender, receiver
 - ✘ each UDP segment handled independently of others

Why is there a UDP?

- ✘ no connection establishment (which can add delay)
- ✘ simple: no connection state at sender, receiver
- ✘ small segment header
- ✘ no congestion control: UDP can blast away as fast as desired

UDP: more

- ✘ often used for streaming multimedia apps
 - ✘ loss tolerant
 - ✘ rate sensitive
- ✘ other UDP uses
 - ✘ DNS
 - ✘ SNMP
- ✘ reliable transfer over UDP: add reliability at application layer
 - ✘ application-specific error recovery!

UDP segment format

UDP checksum

Goal: detect “errors” (e.g., flipped bits) in transmitted segment

Sender:

- ✘ treat segment contents as sequence of 16-bit integers
- ✘ checksum: addition (1’s complement sum) of segment contents
- ✘ sender puts checksum value into UDP checksum field

Receiver:

- ✘ compute checksum of received segment
- ✘ check if computed checksum equals checksum field value:
 - ✘ NO - error detected
 - ✘ YES - no error detected. *But maybe errors nonetheless?*
More later

Outline

- ✘ Transport-layer services
- ✘ Multiplexing and demultiplexing
- ✘ Connectionless transport: UDP
- ✘ **Connection-oriented transport: TCP**
 - ✘ **segment structure**
 - ✘ **reliable data transfer**
 - ✘ **flow control**
 - ✘ **connection management**
- ✘ Principles of congestion control
- ✘ TCP congestion control

TCP: Overview RFCs: 793, 1122, 1323, 2018, 2581

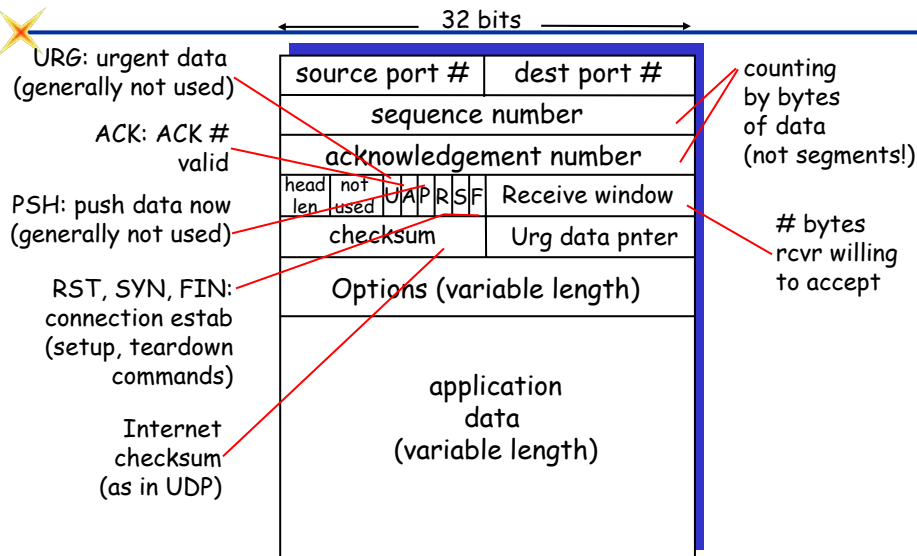

- ✘ **point-to-point:**
 - ✘ one sender, one receiver
- ✘ **reliable, in-order *byte stream*:**
 - ✘ no “message boundaries”
- ✘ **pipelined:**
 - ✘ TCP congestion and flow control set window size
- ✘ **send & receive buffers**
- ✘ **full duplex data:**
 - ✘ bi-directional data flow in same connection
 - ✘ MSS: maximum segment size
- ✘ **connection-oriented:**
 - ✘ handshaking (exchange of control msgs) init's sender, receiver state before data exchange
- ✘ **flow controlled:**
 - ✘ sender will not overwhelm receiver

19

TCP segment structure

Fall '06-02

TELCOM 2310

20

TCP seq. #'s and ACKs

Seq. #'s:

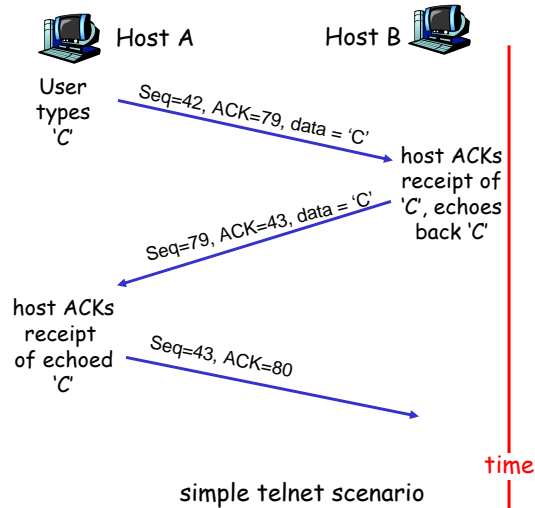

- ✗ byte stream “number” of first byte in segment’s data

ACKs:

- ✗ seq # of next byte expected from other side
- ✗ cumulative ACK

Q: how receiver handles out-of-order segments

- ✗ A: TCP spec doesn’t say, - up to implementor

TCP Round Trip Time and Timeout

Q: how to set TCP timeout value?

- ✗ longer than RTT
 - ✗ but RTT varies
- ✗ too short: premature timeout
 - ✗ unnecessary retransmissions
- ✗ too long: slow reaction to segment loss

Q: how to estimate RTT?

- ✗ **SampleRTT**: measured time from segment transmission until ACK receipt
 - ✗ ignore retransmissions
- ✗ **SampleRTT** will vary, want estimated RTT “smoother”
 - ✗ average several recent measurements, not just current **SampleRTT**

TCP Round Trip Time and Timeout

$$\text{EstimatedRTT} = (1 - \alpha) * \text{EstimatedRTT} + \alpha * \text{SampleRTT}$$

- ✘ Exponential weighted moving average
- ✘ influence of past sample decreases exponentially fast
- ✘ typical value: $\alpha = 0.125$

Example RTT estimation:

RTT: gaia.cs.umass.edu to fantasia.eurecom.fr

TCP Round Trip Time and Timeout

Setting the timeout

- ✘ **EstimatedRTT** plus “safety margin”
 - ✘ large variation in **EstimatedRTT** -> larger safety margin
- ✘ first estimate of how much **SampleRTT** deviates from **EstimatedRTT**:

$$\text{DevRTT} = (1-\beta) * \text{DevRTT} + \beta * |\text{SampleRTT} - \text{EstimatedRTT}|$$

(typically, $\beta = 0.25$)

Then set timeout interval:

$$\text{TimeoutInterval} = \text{EstimatedRTT} + 4 * \text{DevRTT}$$

TCP reliable data transfer

- ✘ TCP creates rdt service on top of IP's unreliable service
- ✘ Pipelined segments
- ✘ Cumulative acks
- ✘ TCP uses single retransmission timer
- ✘ Retransmissions are triggered by:
 - ✘ timeout events
 - ✘ duplicate acks
- ✘ Initially consider simplified TCP sender:
 - ✘ ignore duplicate acks
 - ✘ ignore flow control, congestion control

TCP sender events:

data rcvd from app:

- ✘ Create segment with seq #
- ✘ seq # is byte-stream number of first data byte in segment
- ✘ start timer if not already running (think of timer as for oldest unacked segment)
- ✘ expiration interval: `TimeoutInterval`

timeout:

- ✘ retransmit segment that caused timeout
- ✘ restart timer

Ack rcvd:

- ✘ If acknowledges previously unacked segments
 - ✘ update what is known to be acked
 - ✘ start timer if there are outstanding segments

Fall '06-02

TELCOM 2310

27

```
NextSeqNum = InitialSeqNum
SendBase = InitialSeqNum
```

```
loop (forever) {
  switch(event)
```

```
  event: data received from application above
  create TCP segment with sequence number NextSeqNum
  if (timer currently not running)
    start timer
  pass segment to IP
  NextSeqNum = NextSeqNum + length(data)
```

```
  event: timer timeout
  retransmit not-yet-acknowledged segment with
  smallest sequence number
  start timer
```

```
  event: ACK received, with ACK field value of y
  if (y > SendBase) {
    SendBase = y
    if (there are currently not-yet-acknowledged segments)
      start timer
  }
```

```
  } /* end of loop forever */
```

Fall '06-02

TELCOM 2310

28

TCP sender (simplified)

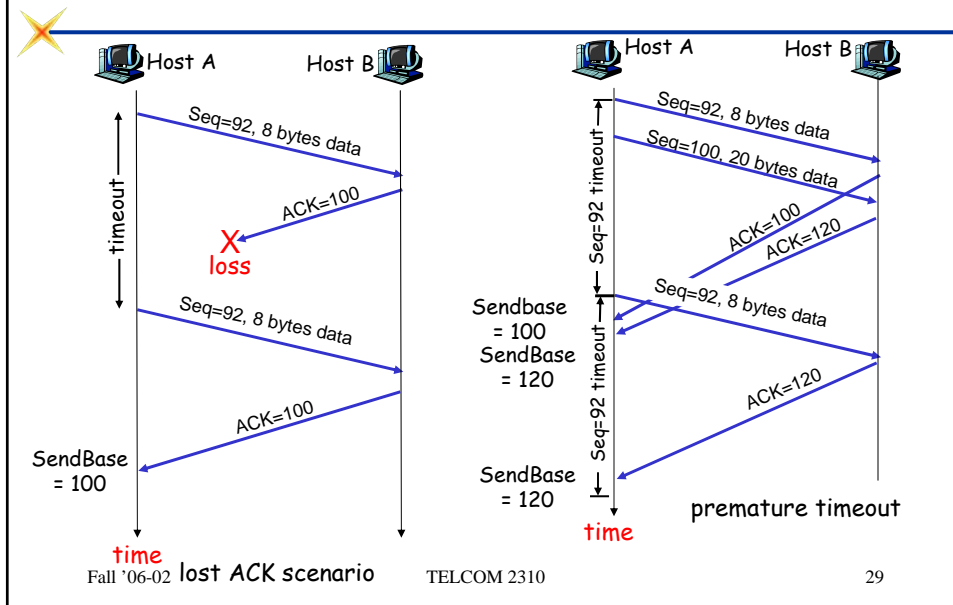

Comment:

- `SendBase-1`: last cumulatively ack'ed byte

Example:

- `SendBase-1 = 71`;
`y = 73`, so the rcvr wants 73+ ;
`y > SendBase`, so that new data is acked

TCP: retransmission scenarios

TCP retransmission scenarios (more)

TCP ACK generation [RFC 1122, RFC 2581]

Event at Receiver	TCP Receiver action
Arrival of in-order segment with expected seq #. All data up to expected seq # already ACKed	Delayed ACK. Wait up to 500ms for next segment. If no next segment, send ACK
Arrival of in-order segment with expected seq #. One other segment has ACK pending	Immediately send single cumulative ACK, ACKing both in-order segments
Arrival of out-of-order segment higher-than-expected seq. # . Gap detected	Immediately send duplicate ACK, indicating seq. # of next expected byte
Arrival of segment that partially or completely fills gap	Immediate send ACK, provided that segment starts at lower end of gap

Fall '06-02

TELCOM 2310

31

Fast Retransmit

- ✘ Time-out period often relatively long:
 - ✘ long delay before resending lost packet
- ✘ Detect lost segments via duplicate ACKs.
 - ✘ Sender often sends many segments back-to-back
 - ✘ If segment is lost, there will likely be many duplicate ACKs.
- ✘ If sender receives 3 ACKs for the same data, it supposes that segment after ACKed data was lost:
 - ✘ **fast retransmit**: resend segment before timer expires

Fall '06-02

TELCOM 2310

32

Fast retransmit algorithm:

```

event: ACK received, with ACK field value of y
  if (y > SendBase) {
    SendBase = y
    if (there are currently not-yet-acknowledged segments)
      start timer
  }
  else {
    increment count of dup ACKs received for y
    if (count of dup ACKs received for y = 3) {
      resend segment with sequence number y
    }
  }
  
```

a duplicate ACK for
already ACKed segment

fast retransmit

Fall '06-02

TELCOM 2310

33

TCP Flow Control

- ✘ receive side of TCP connection has a receive buffer:

- ✘ app process may be slow at reading from buffer

flow control

sender won't overflow receiver's buffer by transmitting too much, too fast

- ✘ speed-matching service: matching the send rate to the receiving app's drain rate

Fall '06-02

TELCOM 2310

34

TCP Flow control: how it works

(Suppose TCP receiver discards out-of-order segments)

✘ spare room in buffer

= **RcvWindow**

= **RcvBuffer - [LastByteRcvd - LastByteRead]**

✘ Rcvr advertises spare room by including value of **RcvWindow** in segments

✘ Sender limits unACKed data to **RcvWindow**

✘ guarantees receive buffer doesn't overflow

TCP Connection Management

Recall: TCP sender, receiver establish "connection" before exchanging data segments

✘ initialize TCP variables:

✘ seq. #s

✘ buffers, flow control info (e.g. **RcvWindow**)

✘ *client*: connection initiator

```
Socket clientSocket = new
Socket("hostname", "port
number");
```

✘ *server*: contacted by client

```
Socket connectionSocket =
welcomeSocket.accept();
```

Three way handshake:

Step 1: client host sends TCP SYN segment to server

✘ specifies initial seq #

✘ no data

Step 2: server host receives SYN, replies with SYNACK segment

✘ server allocates buffers

✘ specifies server initial seq. #

Step 3: client receives SYNACK, replies with ACK segment, which may contain data

TCP Connection Management (cont.)

Closing a connection:

client closes socket:

```
clientSocket.close();
```

Step 1: client end system sends TCP FIN control segment to server

Step 2: server receives FIN, replies with ACK. Closes connection, sends FIN.

Fall '06-02

TELCOM 2310

37

TCP Connection Management (cont.)

Step 3: client receives FIN, replies with ACK.

- ✘ Enters "timed wait" - will respond with ACK to received FINs

Step 4: server, receives ACK. Connection closed.

Note: with small modification, can handle simultaneous FINs.

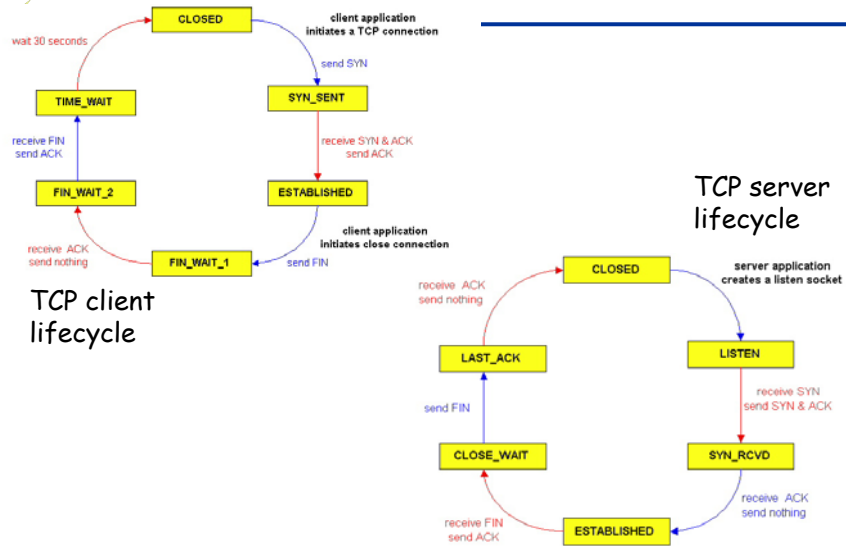

Fall '06-02

TELCOM 2310

38

TCP Connection Management (cont)

Fall '06-02

TELCOM 2310

39

Principles of Congestion Control

Congestion:

- ✘ informally: “too many sources sending too much data too fast for *network* to handle”
- ✘ different from flow control!
- ✘ manifestations:
 - ✘ lost packets (buffer overflow at routers)
 - ✘ long delays (queueing in router buffers)
- ✘ a top-10 problem!

Fall '06-02

TELCOM 2310

40

Causes/costs of congestion: scenario 1

- ✘ two senders, two receivers
- ✘ one router, infinite buffers
- ✘ no retransmission

Fall '06-02

TELCOM 2310

- ✘ large delays when congested
- ✘ maximum achievable throughput

41

Causes/costs of congestion: scenario 2

- ✘ one router, *finite* buffers
- ✘ sender retransmission of lost packet

Fall '06-02

TELCOM 2310

42

Causes/costs of congestion: scenario 2

- ✦ always: $\lambda_{in} = \lambda_{out}$ (goodput)
- ✦ “perfect” retransmission only when loss: $\lambda'_{in} > \lambda_{out}$
- ✦ retransmission of delayed (not lost) packet makes λ'_{in} larger (than perfect case) for same λ_{out}

“costs” of congestion:

- ✦ more work (retrans) for given “goodput”
- ✦ unneeded retransmissions: link carries multiple copies of pkt

Fall '06-02

TELCOM 2310

43

Causes/costs of congestion: scenario 3

- ✦ four senders
 - ✦ multihop paths
 - ✦ timeout/retransmit
- Q:** what happens as λ_{in} and λ'_{in} increase ?

Fall '06-02

TELCOM 2310

44

Causes/costs of congestion: scenario 3

Another “cost” of congestion:

- ✘ when packet dropped, any “upstream transmission capacity used for that packet was wasted!

Fall '06-02

TELCOM 2310

45

Approaches towards congestion control

Two broad approaches towards congestion control:

End-end congestion control:

- ✘ no explicit feedback from network
- ✘ congestion inferred from end-system observed loss, delay
- ✘ approach taken by TCP

Network-assisted congestion control:

- ✘ routers provide feedback to end systems
 - ✘ single bit indicating congestion (SNA, DECbit, TCP/IP ECN, ATM)
 - ✘ explicit rate sender should send at

Fall '06-02

TELCOM 2310

46

TCP Congestion Control

- ✘ end-end control (no network assistance)
- ✘ sender limits transmission:
 $\text{LastByteSent} - \text{LastByteAked} \leq \text{CongWin}$

- ✘ Roughly,

$$\text{rate} = \frac{\text{CongWin}}{\text{RTT}} \text{ Bytes/sec}$$

- ✘ **CongWin** is dynamic, function of perceived network congestion

How does sender perceive congestion?

- ✘ loss event = timeout *or* 3 duplicate acks
- ✘ TCP sender reduces rate (**CongWin**) after loss event

three mechanisms:

- ✘ AIMD
- ✘ slow start
- ✘ conservative after timeout events

Fall '06-02

TELCOM 2310

47

TCP AIMD

multiplicative decrease: cut **CongWin** in half after loss event

additive increase: increase **CongWin** by 1 MSS every RTT in the absence of loss events: *probing*

Long-lived TCP connection

Fall '06-02

TELCOM 2310

48

TCP Slow Start

- ✘ When connection begins, **CongWin** = 1 MSS
 - ✘ Example: MSS = 500 bytes & RTT = 200 msec
 - ✘ initial rate = 20 kbps
- ✘ available bandwidth may be \gg MSS/RTT
 - ✘ desirable to quickly ramp up to respectable rate
- ✘ When connection begins, increase rate exponentially fast until first loss event

TCP Slow Start (more)

- ✘ When connection begins, increase rate exponentially until first loss event:
 - ✘ double **CongWin** every RTT
 - ✘ done by incrementing **CongWin** for every ACK received
- ✘ **Summary:** initial rate is slow but ramps up exponentially fast

Refinement

- ✘ After 3 dup ACKs:
 - ✘ **CongWin** is cut in half
 - ✘ window then grows linearly
- ✘ But after timeout event:
 - ✘ **CongWin** instead set to 1 MSS;
 - ✘ window then grows exponentially
 - ✘ to a threshold, then grows linearly

Philosophy:

- 3 dup ACKs indicates network capable of delivering some segments
- timeout before 3 dup ACKs is "more alarming"

Refinement (more)

Q: When should the exponential increase switch to linear?

A: When **CongWin** gets to 1/2 of its value before timeout.

Implementation:

- ✘ Variable Threshold
- ✘ At loss event, Threshold is set to 1/2 of CongWin just before loss event

Summary: TCP Congestion Control

- ✘ When **CongWin** is below **Threshold**, sender in **slow-start** phase, window grows exponentially.
- ✘ When **CongWin** is above **Threshold**, sender is in **congestion-avoidance** phase, window grows linearly.
- ✘ When a **triple duplicate ACK** occurs, **Threshold** set to **CongWin/2** and **CongWin** set to **Threshold**.
- ✘ When **timeout** occurs, **Threshold** set to **CongWin/2** and **CongWin** is set to 1 MSS.

TCP Fairness

Fairness goal: if K TCP sessions share same bottleneck link of bandwidth R , each should have average rate of R/K

Why is TCP fair?

Two competing sessions:

- ✘ Additive increase gives slope of 1, as throughput increases
- ✘ multiplicative decrease decreases throughput proportionally

Fall '06-02

TELCOM 2310

55

Fairness (more)

Fairness and UDP

- ✘ Multimedia apps often do not use TCP
 - ✘ do not want rate throttled by congestion control
- ✘ Instead use UDP:
 - ✘ pump audio/video at constant rate, tolerate packet loss
- ✘ Research area: TCP friendly

Fairness and parallel TCP connections

- ✘ nothing prevents app from opening parallel cncctions between 2 hosts.
- ✘ Web browsers do this
- ✘ Example: link of rate R supporting 9 cncctions;
 - ✘ new app asks for 1 TCP, gets rate $R/10$
 - ✘ new app asks for 11 TCPs, gets $R/2$!

Fall '06-02

TELCOM 2310

56

Delay modeling

Q: How long does it take to receive an object from a Web server after sending a request?

Ignoring congestion, delay is influenced by:

- ✘ TCP connection establishment
- ✘ data transmission delay
- ✘ slow start

Notation, assumptions:

- ✘ Assume one link between client and server of rate R
- ✘ S : MSS (bits)
- ✘ O : object size (bits)
- ✘ no retransmissions (no loss, no corruption)

Window size:

- ✘ First assume: fixed congestion window, W segments
- ✘ Then dynamic window, modeling slow start

Fixed congestion window (1)

First case:

$WS/R > RTT + S/R$: ACK for first segment in window returns before window's worth of data sent

$$\text{delay} = 2RTT + O/R$$

Fixed congestion window (2)

Second case:

- ✘ $WS/R < RTT + S/R$: wait for ACK after sending window's worth of data sent

$$\text{delay} = 2RTT + O/R + (K-1)[S/R + RTT - WS/R]$$

TCP Delay Modeling: Slow Start (1)

Now suppose window grows according to slow start

Will show that the delay for one object is:

$$\text{Latency} = 2RTT + \frac{O}{R} + P \left[RTT + \frac{S}{R} \right] - (2^P - 1) \frac{S}{R}$$

where P is the number of times TCP idles at server:

$$P = \min\{Q, K - 1\}$$

- where Q is the number of times the server idles if the object were of infinite size.
- and K is the number of windows that cover the object.

TCP Delay Modeling: Slow Start (2)

Delay components:

- 2 RTT for connection estab and request object
- O/R to transmit object
- time server idles due to slow start

Server idles:

$$P = \min\{K-1, Q\} \text{ times}$$

Example:

- $O/S = 15$ segments
- $K = 4$ windows
- $Q = 2$
- $P = \min\{K-1, Q\} = 2$

Server idles $P=2$ times

Fall '06-02

TCP Delay Modeling (3)

$$\frac{S}{R} + RTT = \text{time from when server starts to send segment}$$

until server receives acknowledgement

$$2^{k-1} \frac{S}{R} = \text{time to transmit the } k\text{th window}$$

$$\left[\frac{S}{R} + RTT - 2^{k-1} \frac{S}{R} \right]^+ = \text{idle time after the } k\text{th window}$$

$$\begin{aligned} \text{delay} &= \frac{O}{R} + 2RTT + \sum_{p=1}^P \text{idleTime}_p \\ &= \frac{O}{R} + 2RTT + \sum_{k=1}^P \left[\frac{S}{R} + RTT - 2^{k-1} \frac{S}{R} \right] \\ &= \frac{O}{R} + 2RTT + P \left[RTT + \frac{S}{R} \right] - (2^P - 1) \frac{S}{R} \end{aligned}$$

Fall '06-02

TELCOM 2310

62

TCP Delay Modeling (4)

Recall K = number of windows that cover object

How do we calculate K ?

$$\begin{aligned} K &= \min\{k : 2^0 S + 2^1 S + \dots + 2^{k-1} S \geq O\} \\ &= \min\{k : 2^0 + 2^1 + \dots + 2^{k-1} \geq O/S\} \\ &= \min\{k : 2^k - 1 \geq \frac{O}{S}\} \\ &= \min\{k : k \geq \log_2(\frac{O}{S} + 1)\} \\ &= \left\lceil \log_2(\frac{O}{S} + 1) \right\rceil \end{aligned}$$

Calculation of Q , number of idles for infinite-size object, is similar (see HW).

Summary

- ✘ principles behind transport layer services:
 - ✘ multiplexing, demultiplexing
 - ✘ reliable data transfer
 - ✘ flow control
 - ✘ congestion control
- ✘ instantiation and implementation in the Internet
 - ✘ UDP
 - ✘ TCP

Next:

- ✘ leaving the network “edge” (application, transport layers)
- ✘ into the network “core”
